Spec-Driven Development Suite

A reusable workflow for AI-assisted software delivery

Connect requirements, technical decisions, implementation tasks and verification evidence. Project records keep context available when requirements change, work moves between people or development resumes after a pause.

Where it helps

Team need	How the suite helps
Agree on the outcome	Defines scope and observable acceptance checks
Handle a requirement change	Identifies affected decisions, tasks and evidence
Continue or hand over work	Reconciles saved progress with the current implementation
Review completion	Connects claims to recorded checks and makes gaps visible

What teams receive

Twelve focused skills, a working example, installation and recovery tools, and local tools for checking records and recording test output. Use the full workflow or request one stage. Teams retain their existing conventions and release controls.

Getting started

Follow README.md in the repository to install for your assistant, run the example, then request a feature or stage in normal language. Suite tools require Python 3.10+ and the standard library.

Validation and compatibility

Recorded tool checks: 95 passed, four environment-related skips. A separate study recorded 36/36 expected skill-selection outcomes in one model environment. Codex and Claude Code installation layouts are included. Detailed methods, versions and assistant coverage appear in docs/RELEASE-REPORT.md.
